## 1 1.0 Scope and Purpose

2 The subfamily Lymantriinae, also commonly referred to as tussock moths, but hereafter referred  
3 to as lymantriids, is a very important group of insect defoliators of forest and agricultural plant  
4 species throughout the world. Increases in global trade coupled with the diversity of lymantriids  
5 and the breadth of potential hosts make the risk of introduction and spread of some lymantriid  
6 species high in the NAPPO region. The economic impact of establishment of some lymantriid  
7 species in the NAPPO region (e.g., the Asian gypsy moth (AGM) *Lymantria dispar asiatica*) could  
8 be significant.

9  
10 AGM is a quarantine significant pest in all three NAPPO member countries. Potential pathways  
11 for introduction of AGM include cargo shipments from marine vessels and other types of  
12 conveyances normally associated with international trade. NAPPO has developed a regional  
13 standard (RSPM 33 – *Guidelines for regulating the movement of ships and cargo from areas*  
14 *infested with the Asian gypsy moth*) to help reduce the risk of introducing AGM by certifying  
15 marine vessels moving commodities from regulated countries to the NAPPO region during the  
16 specified risk periods (SRP)<sup>1</sup>.

17  
18 However, the interception of egg masses of other lymantriids (*Lymantria mathura*, *L. xyliina* and  
19 *L. lucescens*) in Canada and the United States (U.S.) on vessels from Asia clearly illustrates a  
20 potential additional threat and the need for NAPPO to examine the potential for introduction of  
21 other lymantriid species into the NAPPO region. This study will assemble data on other  
22 economically important lymantriid species that can be used to support regulatory agencies as  
23 they develop programs and guidelines aimed at reducing the risk of introduction of lymantriid  
24 species of economic importance into the NAPPO region. The results of this study will also provide  
25 necessary information for future amendments to RSPM 33.

26  
27 The objectives of this project are to support regulatory decisions by NAPPO member countries  
28 by:

- 29 1. providing a general perspective concerning exotic lymantriid species with the highest risk  
30 of introduction and potential impact to the NAPPO region arriving via international trade  
31 or other introduction pathways;
- 32 2. developing a risk assessment methodology that can be used to quickly screen large  
33 numbers of lymantriid species and efficiently characterize the pest risk posed by these  
34 species;
- 35 3. identifying and ranking lymantriid species based on their likelihood of introduction, spread  
36 and potential economic and/or environmental impact.

## 37 2.0 Taxonomy and Systematics

38 To date there has been no worldwide revision of the lymantriids. Most of the taxonomic and  
39 systematic development has been through regional faunal inventories, for example, the *Moths of*  
40 *North America* and the *Moths of Borneo* (Holloway 1999; Ferguson, 1978; Pogue and Schaefer,  
41 2007). More recently, phylogenetic studies have re-classified the family Lymantriidae as the  
42 subfamily Lymantriinae of the recently created family Erebidae (Zahiri *et al.*, 2010; Zahiri *et al.*,  
43 2012), and there have been worldwide generic revisions of *Calliteara* (Witt and Trofimova 2016)  
44 and *Lymantria* (Schintlmeister, 2004).

---

<sup>1</sup> Specified risk period defined as the time in each regulated area when there is a high risk of moth flight and egg mass deposition on marine vessels.

## 1 2.1 Number of Species and their Distribution

2 Lymantriids are an important group within the Erebiidae family with species found in all continents  
3 except Antarctica. Most of the species diversity occurs in the tropical areas of Africa, India and  
4 Southeast Asia. Lymantriid species diversity in Madagascar is high, with 258 species registered,  
5 many of which are endemic (Griveaud, 1977). Lymantriids are noticeably absent in islands in New  
6 Zealand, the Antilles, Hawaii, and most of the South Pacific islands except for Fiji, New Caledonia  
7 and other islands in the Southeast (Ferguson, 1978; Holloway, 1979 and Schaefer, 1989).

8 Heppner (1991) suggested dividing the 2416 species of the formerly Lymantriidae family  
9 according to the regions where they are present, classifying them as follows: Afrotropical (1004),  
10 Oriental east to Moluccas (742), Australian including New Guinea and islands to the East (255),  
11 Palearctic (203), Neotropical (180) and Nearctic (32).

12 As a result of several studies on regional fauna performed from the 1950's to the beginning of the  
13 1980's, which have helped illustrate the abundance or scarcity of lymantriid in some areas, a  
14 tentative catalogue of lymantriid species including about 355 genera and 3065 known species  
15 (Schaefer, 1989) has been developed. Genera with 20 or more species is considered a "main  
16 genera". In this catalog, 21 genera have 2159 species, or over 70% of the overall known species  
17 (Schaefer, 1989).

## 18 3.0 Characteristics and Biology of Lymantriids

19 Lymantriids are characterized by the presence of tufts along the back of the larvae. Adults typically  
20 have cryptic coloration, which provides good camouflage for blending with the tree bark, lichens,  
21 or leaves where they are typically resting. Adults are dimorphic in most lymantriid species with  
22 males normally smaller and darker than females and with very prominent bi-pectinate antennae.  
23 Adults of many species are monochromatic (white or yellow tone). Lymantriid larvae are usually  
24 very colorful, with a large group of setae forming tufts. Some of them (for example, many species  
25 of the genus *Euproctis*) have urticating hairs which may cause serious allergic reactions if they  
26 come in contact with human skin. Larvae also have two medio-dorsal glands on abdominal  
27 segments 6 and 7. These glands are usually bright and colorful with red, orange or yellow tones.  
28 It is believed that the glands are used as a defense mechanism (Schaefer, 1989).

29  
30 There are numerous examples of pest species within the lymantriid group, e.g., Gypsy moth  
31 (*Lymantria dispar*), brown tail moth (*Euproctis chrysorrhoea*), painted apple moth (*Orgyia*  
32 *anartoides*) and nun moth (*Lymantria monacha*). These pest species have a high fecundity,  
33 producing large numbers of offspring in a generation. The ability of females from some species  
34 to fly, egg masses being transported long distances using different pathways, e.g., by deposition  
35 on ships or cargo, and the capacity of 1<sup>st</sup> instar larvae to spread long distances using the wind  
36 (ballooning), results in spread to new areas. Some lymantriid species undergo cyclical outbreaks  
37 with large-scale defoliation of their host plants. Outbreaks have also been associated with a high  
38 incidence of dermatitis and other skin conditions due to the urticating nature of the larval setae.

39  
40 Lymantriid larvae are highly polyphagous and many species within this subfamily are pests of  
41 agricultural and forest species. Adults do not feed and as such have a short lifespan of a few  
42 weeks. Some species have wingless females. In most species the females have a silk tuft on the  
43 posterior end of the abdomen used to cover and protect egg masses. Most species are nocturnal,  
44 univoltine and many are attracted to light (Grundy and Lowe, 2010; Herbison-Evans and Crossley,  
45 2017; Waring and Townsend, 2017).

#### 1 **4.0 Hosts of Economic and Environmental Concern**

2 Lymantriids are some of the world's most destructive forest pests (Pogue and Schaefer, 2007).  
3 They can also cause severe damage to agriculture and in urban settings. Their host plants are  
4 better known in temperate regions of the Northern Hemisphere. In tropical areas, where there is  
5 a high diversity of plant species, feeding habits are not well documented. However, in general  
6 terms, forest and shade trees serve as the main source of food. Shrubs, grapevines, herbs and  
7 grasses are less important. At least two species feed on lichens and one is known to feed on  
8 mistletoe (Schaefer, 1989).

9  
10 Species within the genus *Lymantria* alone are known to feed on over 150 primary hosts, mainly  
11 forest species such as: alder (*Alnus* spp.), poplar (*Populus* spp.), birch (*Betula* spp), willow (*Salix*  
12 spp.), hawthorn (*Crataegus* spp.), larch (*Larix* spp.), tilia (*Tilia* spp.) and oak (*Quercus* spp.). Last  
13 instar larvae prefer species such as pine (*Pinus* spp.), beech (*Fagus* spp.), juniper (*Juniperus*  
14 spp.), chestnut (*Castanea* spp.) and *Tsuga* spp, among others.

15  
16 In addition to the forest species mentioned above, they can feed on other species of agricultural  
17 concern, such as: plum (*Prunus domestica*), peach (*Prunus persica*), almond (*Prunus* spp.), apple  
18 (*Malus domestica*) and pistachio (*Pistacia vera*) (Fact sheet No. 65, May 2019. SADER-  
19 SENASICA, Mexico).

#### 20 **5.0 Regulatory and phytosanitary framework**

21 NAPPO develops science-based regional standards which are intended to protect agricultural,  
22 forest and other plant resources of North America against regulated plant pests, while also  
23 facilitating safe trade. NAPPO's Regional Standard for Phytosanitary Measures 33 (RSPM 33)  
24 provides member countries with guidelines to minimize the entry and establishment of the Asian  
25 Gypsy Moth (AGM) in North America. RSPM 33 describes risk management options for ships  
26 leaving ports from AGM regulated countries during the specified risk periods (SRP). It also  
27 describes the necessary measures for ships coming from infested areas or in-transit in regulated  
28 countries during the SRPs and destined to North America.

29  
30 NAPPO countries have established regulatory measures and directives to minimize the risk of  
31 introduction of lymantriid species, especially the Asian gypsy moth, via vessels or high-risk  
32 commodities like wood.

#### 33 **5.1 Canada**

34 Lymantriid species listed in the Canadian Food Inspection Agency (CFIA) "Regulated Pest" list  
35 include *Euproctis chrysorrhoea*, *Lymantria albescens*, *Lymantria dispar*, *Lymantria dispar*  
36 *asiatica*, *Lymantria dispar japonica*, *Lymantria mathura*, *Lymantria monacha*, *Lymantria postalba*,  
37 *Lymantria umbrosa* and *Orgyia anartoides*.

38  
39 More specifically, two policy directives have been adopted by CFIA to prevent the introduction  
40 and spread of gypsy moth. Directive D-95-03 describes regulatory measures to prevent the entry  
41 of the Asian strains of gypsy moth (*Lymantria dispar*, *L. albescens*, *L. postalba* and *L. umbrosa*)  
42 on vessels and their establishment in Canada. Domestically, directive D-98-09 lists the  
43 requirements for the movement within Canada, export from Canada to the United States and  
44 import from U.S. of regulated articles which may harbor any life stage of the European strain of  
45 gypsy moth. Regulated articles under this directive include nursery stock, Christmas trees,  
46 forestry products with bark attached, all outdoor household articles, military, recreational and

1 personal vehicles and equipment. Additionally, many other policy directives, for instance directive  
2 D-01-12 on importation and movement of firewood, contain requirements aimed at preventing the  
3 introduction and spread of quarantine pests, including gypsy moth.

## 4 **5.2 United States**

5 In the United States, the genus *Lymantria* along with the species *L. dispar*, *L. mathura*, *L.*  
6 *monacha*, and *L. xyliina* are considered actionable pests at U.S. ports of entry (PestID, 2018). In  
7 addition, the United States maintains a domestic quarantine for gypsy moth infested states (7  
8 CFR § 301.45, 2018). This quarantine regulates the movement of commodities likely to move  
9 gypsy moth life stages, e.g. logs, mobile homes, and Christmas trees, from infested to un-infested  
10 areas.

11  
12 The United States also regulates at-risk articles from areas in Canada infested with gypsy moth  
13 (7 CFR § 319.77, 2018; 7 CFR § 330.301, 2018; USDA, 2017, 2018). Gypsy moth host material  
14 from Canada is regulated under 7 CFR § 319.77 and at-risk Canadian stone and quarry products  
15 are regulated under 7 CFR § 330.301.

## 16 **5.3 Mexico**

17 Mexico has Official Regulations (NOMs), through which phytosanitary requirements are  
18 established to comply with the importation of some forestry products. NOMs provide a list of  
19 regulated pests for those commodities that are of quarantine concern. European and Asiatic  
20 strains, *Lymantria dispar*, *L. dispar asiatica* and *L. dispar japonica*, are the only lymantriid species  
21 named in the NOMs. These regulations are listed below.

22 Mexican Official Regulation NOM-013-SEMARNAT-2010 regulates the importation of natural  
23 Christmas trees belonging to the genera *Pinus* and *Abies* and the species *Pseudotsuga menziesii*.

24 Mexican Official Regulation NOM-016-SEMARNAT-2013 regulates the importation of new sawn  
25 wood, and “the Agreement to determine the list of invasive exotic species for Mexico,” published  
26 at the Federal Official Gazette on December 7, 2016 lists *Orgyia pseudotsugata* and *Lymantria*  
27 *dispar* as two exotic lymantriid species of concern for Mexico.

28 In Mexico, the family Erebidae, subfamily Lymantriinae is not widely studied in terms of species  
29 diversity, biology and habits, therefore little is known about the species diversity in Mexico.

## 30 **6.0 Likelihood of introduction and spread of lymantriid species in the NAPPO** 31 **Region. Information needs and gaps.**

32 The likelihood of introduction of lymantriids into the NAPPO region is high due to the high volume  
33 of shipping containers and vessels moving from regulated countries to the NAPPO region,  
34 movement of other commodities, and the large number of host species in the NAPPO region.

35  
36 There is evidence that lymantriids have been introduced into the NAPPO region and have become  
37 economically important pests. For example, gypsy moth *Lymantria dispar* (L.), was intentionally  
38 introduced into Massachusetts, in the United States in the late 1860s from Europe for silk  
39 production (Liebhold *et al.*, 1989). Since that time, it has become widely distributed (Ref. CABI  
40 2020) and has caused widespread damage to forest trees. *Euproctis chrysorrhoea* (L.), another  
41 serious pest of forest and shade trees in North America, was accidentally introduced into  
42 Massachusetts in 1897 from Europe. It was first detected in the Boston, Massachusetts area at

1 the beginning of 1890, and since then has spread to parts of the Eastern United States and  
2 Canada (Triplehorn and Johnson, 2005) (CABI 2020).

3  
4 All life stages of Asian gypsy moth (egg masses, larvae, pupae, and adults) and other lymantriid  
5 species (*Lymantria mathura*, *Leucoma salicis* and *Lymantria xyliana* among others), have been  
6 intercepted in the NAPPO region primarily during maritime port inspections of ships and shipping  
7 containers from Asia (Russia, Japan, China, Philippines and Korea) and Europe. Interceptions  
8 of *Lymantria dispar* in Canada have also been reported on Christmas trees, propagative plant  
9 material and grain from the U.S. To a lesser extent, egg masses and pupal cases have been  
10 intercepted on/in passenger baggage at airport inspection points in the United States and Canada  
11 AQAS, 2019). Other pathways based on inspection data include movement of military and  
12 agricultural equipment, cut flowers, nursery stock, wood (wood packaging) and personal effects  
13 from countries where regulated species of lymantriids are found. Other less-documented  
14 pathways include e-commerce, smuggling, and other intentional or non-intentional movement of  
15 human-derived activities. The large number of interceptions reported in maritime vessels and  
16 shipping containers suggests that this is the most important pathway for entry into the NAPPO  
17 region.

18  
19 The economic and environmental impact of the introduction and spread of lymantriid species into  
20 the NAPPO region could be significant due to the large number of potentially affected host species  
21 and suitable climatological conditions found in North America. A simple, efficient and quick risk  
22 assessment model would facilitate characterization and prioritization of the risks posed to North  
23 America. The model would improve our understanding of the species of major concern for the  
24 NAPPO region and inform decision making by North American plant health regulatory agencies.  
25 In addition, the information gathered could be used to amend the existing NAPPO regional  
26 standard on AGM, RSPM 33, by expanding the number of species and/or modifying the specified  
27 risk periods for the regulated areas.

## 28 **7.0 Approach & Methods**

### 29 **7.1 Screening for species of potential concern to the NAPPO region**

30 A target list of 189 lymantriid species of concern for the NAPPO region was generated for risk  
31 analyses by cross-referencing a host genera list of economic importance in each NAPPO  
32 member country against the lepidopteran HOST plant databases ([http://www.nhm.ac.uk/our-](http://www.nhm.ac.uk/our-science/data/hostplants/)  
33 [science/data/hostplants/](http://plants.usda.gov/java/) and <http://plants.usda.gov/java/> ).  
34 The distribution of selected species was determined by web-crawling the FUNET museum  
35 archives and databases using a Python script  
36 (<http://www.nic.funet.fi/pub/sci/bio/life/insecta/lepidoptera/ditrysia/noctuoidea/lymantriidae/>  
37 ). Available information, e.g., scientific literature, interception data, biological aspects (available for  
38 each of the species, e.g., geographic distribution, feeding habits, hosts, attraction to light, mode  
39 of spreading, damage to important agricultural and forestry plants species or humans) and host  
40 data was also considered when selecting species for risk analyses.

### 41 **7.2 Risk analysis model and data sheet**

42 With the information gathered as indicated in the previous section, a risk analysis data sheet was  
43 designed to allow for rapid screening and identification of lymantriid species based on their  
44 introduction and spread potential, impact into the NAPPO region and the potential economic and  
45 environmental damage (Appendix 1). Data sheet questions were based on expert group

1 discussions, scientific information, and information gathered from other pest risk assessments  
2 obtained from databases and scientific literature revisions (Section 7.1).

3  
4 The first section of the data sheet determines 1) known geographic distribution, 2) the amount of  
5 area in each NAPPO country that is at risk for establishment based on climate, and, 3) if the  
6 lymantriid species feeds on economic or environmental hosts of concern to the NAPPO region.  
7 To characterize the area in each NAPPO country at risk for establishment for each species, the  
8 species' known geographic distribution and the Köppen-Geiger climate classification system were  
9 used. The Köppen-Geiger system delineates geographic areas into climate regions based on  
10 temperature and precipitation patterns (Peel *et al.*, 2007)). Predominant Köppen-Geiger classes  
11 occurring within each lymantriid species' known geographic distribution (based on published data)  
12 and the geospatial data layer reported by Peel *et al.* (2007) were determined first. (See Appendix  
13 2; Figure 1). The areas of those classes in each NAPPO country were summed using GIS. The  
14 percentage of climatologically suitable area within each NAPPO country was determined by  
15 dividing the total climatologically suitable area by the NAPPO country's total area and then  
16 multiplying by 100. The result provided an estimate of each NAPPO country's area at risk for  
17 establishment by each lymantriid species in percentage terms. Scientific and technical sources  
18 were used to determine if the lymantriid species feed on economic or environmental hosts of  
19 concern to the NAPPO region (see Appendix 3 for useful data sources).

20  
21 The next data sheet section consists of eight questions and associated numerical scores that  
22 evaluate the lymantriid species' capacity for introduction and spread. We provide guidance and  
23 data sources for answering these questions in Appendix 3. The eight questions are as follows:

- 24  
25 1) Are adult females attracted to light? (*This question identifies species that are likely to be*  
26 *flying during SRPs and might infest vessels and/or their cargo.*)  
27 2) Has the species been reported as a contaminant in its overwintering stage? (*This question*  
28 *identifies species that are likely to move via trade into the NAPPO region.*)  
29 3) Is the species reported to cause damage resulting in economic or environmental losses in  
30 its native range? (*This question identifies species that are likely to be pests if introduced.*)  
31 4) Does the species have larvae capable of ballooning? (*This question identifies species with*  
32 *larval stages that are capable of moving from ships to surrounding areas around ports and*  
33 *are likely to spread in the larval stage if introduced.*)  
34 5) Does the species have adult females capable of flight? (*This question identifies species*  
35 *capable of flying and laying egg masses which would facilitate movement in trade and*  
36 *spread if introduced into the NAPPO region.*)  
37 6) Does the species' life history include a dormant stage to withstand harsh environmental  
38 conditions? (*This question identifies species that are likely survive shipment to the NAPPO*  
39 *region and persist once introduced.*)  
40 7) Is the species capable of natural dispersal farther than 1km/year? (*This question identifies*  
41 *species that are likely to spread long distances via one or more life stages once*  
42 *introduced.*)  
43 8) Is the species reported to have allergenic properties? (*This question identifies species that*  
44 *might cause harmful health-related impacts once introduced.*)  
45

46 Scores were assigned with 1 if the answer was yes, -1 if no, and 0 if no information is available,  
47 with exceptions noted as follows. For question 2, a value of 2 was assigned if the answer was

1 “Yes” and it moves in trade, 1 if yes and it moves by non-trade related means, -2 if no, and 0 if no  
 2 information is available. For question 3, a score of 3 was assigned if it causes severe damage, 2  
 3 if it causes moderate damage, 1 if it causes low damage, -2 if it causes negligible damage, and 0  
 4 if no information is available. Questions 2 and 3 were given more weight because we considered  
 5 them to have a greater effect on the likelihood of a lymantriid species being introduced and  
 6 becoming a pest.

7  
 8 Based on the proposed risk score system, a maximum value of 11 and a minimum value of -10  
 9 can be assigned to species. The highest score indicates the highest likelihood that a species  
 10 could potentially get introduced, spread and become a pest given the scoring parameters used in  
 11 the risk analysis. Risk categories were established as follows:

Risk Category	Score Range	Justification
High	6 or higher	Species with female moths attracted to light and capable of flight, known to cause substantial economic and/or environmental damage, with the capacity to spread very quickly in large areas, that can be introduced through different pathways.
Medium	1 to 5	Species known to cause limited economic and/or environmental impact, with females not necessarily attracted to light, and limited capacity to spread.
Low	0 or lower	Species with little to no economic or environmental impact. Low scores may also occur when little or no information is available regarding a lymantriid species.

14 **7.3 Uncertainty Analysis**

15  
 16 To characterize uncertainty in the data sheet results we first calculated the percent of the time a  
 17 question was answered “0” for each of the 81 analyzed species. We then calculated the average  
 18 percentage of “0” responses for all eight questions for the 81 analyzed species along with the  
 19 standard deviation and 95% confidence interval.

20 **8.0 Results and Discussion**

21 **8.1 General findings**

22 A risk assessment data sheet that can be useful as an initial filter to identify lymantriid species of  
 23 most concern to the NAPPO region was developed.

24

1 Low, medium and high risk categories, based on the final scores, indicate the highest risk species  
2 for the NAPPO region, and facilitate prioritization for further research and for future amendments  
3 to regulatory programs.

4  
5 The lack of information (e.g., biology and distribution) and the difficulty in translating the available  
6 information on certain lymantriid species to risk scores and possibly risk categories suggests the  
7 need for more information and/or more research. This is primarily an issue affecting species  
8 classified as “low risk” with scores between -10 and 0, because for most parameters evaluated,  
9 the information gathered for “low risk” species was insufficient. There is also the possibility that  
10 some species are misclassified as “low risk” because of insufficient data.

11 Conversely, the probability of misclassifying “high risk” species tends to be lower. Risk scores for  
12 “high risk” species tend to be more reliable because insects that cause economic or environmental  
13 damages are more widely studied and reliable information is available.

14 For this project 81 lymantriid species were evaluated and the highest risk species were identified  
15 (Table 1; Appendix 5). The total risk scores ranged from -4 to 11 (Figure 2). The average total  
16 risk score and standard deviation was  $2.43 \pm 2.99$ . The 95 percent confidence interval for the  
17 average was 1.77 to 3.09. Twelve species had a total risk score of “High” including *Lymantria*  
18 *monacha*, *L. mathura*, *L. lunata* and *L. xyliina*, all of which have been intercepted at ports of entry  
19 in the NAPPO region.

20  
21 These results can serve as a support tool for inspectors and to inform phytosanitary officials within  
22 the NAPPO region. For example, our data sheets can be used to inform risk assessments, port  
23 policy, surveys, and to update RSPM 33. Also, the mean total score provides a risk estimate for  
24 a typical lymantriid species which could serve as a baseline for evaluating the riskiness of  
25 lymantriid species that are analyzed with this data sheet in the future as more information  
26 becomes available

## 27 **8.2 Characterizing Uncertainty**

28 Many of the risk characterization questions for lymantriid species were scored zero to indicate  
29 uncertainty due to a lack of information. For example, on average, a question scored zero  $66\% \pm$   
30  $4.3$  (95% confidence interval = 49% to 82%) of the time for the 81 lymantriid species analyzed.  
31 Also, there were two questions: 1) “Reports of contaminant during pest’s overwintering stage” and  
32 2) “Capable of dispersing naturally more than 1km/year”, which scored zero for 83% and 90% of  
33 the time respectively (Figure 3). One of the potential uses of our analysis is identifying data gaps  
34 in lymantriid biology that can be used to inform future research.

## 35 **9.0 Conclusions, recommendations and next steps**

36 We recommend additional analyses on the highest risk lymantriid species to further inform policy  
37 and operational decisions in the NAPPO region. We suggest:

- 38  
39
- 40 • focusing research and sharing interception information on the questions that scored  
41 uncertain which will allow us to provide useful information to risk assessors and decision  
42 makers;
  - 43 • developing training materials for inspectors and regulatory tools for decision-makers  
44 based on the results presented herein.

1 Our analysis compliments the work being done by the NAPPO Asian gypsy moth Expert Group  
2 in that it identifies other high risk lymantriids that could move in trade. We suggest updating RSPM  
3 33 to include the highest risk species identified in this study and incorporating associated risk  
4 management recommendations after more information is gathered from the species we have  
5 determined to be high risk, based on the flight periods and/or biological information that is relevant  
6 to regulatory actions.  
7

8 Lastly, if other groups such as NPPOs and academia adopt or improve our approach, there is the  
9 potential to continue evaluating additional lymantriid species for pest risk. A database housing  
10 this information would be useful to NPPOs needing to prioritize risk management activities against  
11 members of this subfamily.

2

1 **Appendix 2. NAPPO Climate Risk Analysis Based on Köppen-Geiger Climate**  
2 **Zones**

3 Purpose: Characterize how much of the NAPPO region is at risk for establishment by a lymantriid  
4 species based on similar climate characteristics and known global occurrences.

5 Method Used: Query known lymantriid geospatial occurrence records Good data sources for  
6 georeferenced species data include the Global Biodiversity Information Facility  
7 (<https://www.gbif.org>) and iNaturalist (<https://www.inaturalist.org>). By species, intersect the  
8 occurrence records with Köppen-Geiger climate zones (Figure 1) and report the climate types  
9 affected and which NAPPO countries have similar climate types to the known occurrences.  
10 Climate match percentage is calculated based on matching climate type in native range, as a  
11 percentage of the country's total area.

12

World map of Köppen-Geiger climate classification

**Figure 1.** Global distribution map of the updated (2007) Köppen-Geiger climate zones. Source: <http://people.eng.unimelb.edu.au/mpeel/koppen.html>

1 **Appendix 3. Tips/Notes on Answering Questions in the Lymantriid Decision**  
2 **Process**

3 Overall suggestion: Consider reliability of the report when answering the questions (such as  
4 journal publication vs museum record vs internet report). Less credible sources will be answered  
5 as “uncertain” but make notes in the comments section, so we do not discard any information.

6 Naming Convention: Spp, Status, Score, Language (e/s)

7 Example: *Arctornis alba* Draft -1-e

8 **1. Amount of the NAPPO region with similar climate types to where the species**  
9 **occurs.**

10 We have provided appendix 1 to help answer this question for a large number of lymantriid.  
11 May also use taxonomic databases like Finlands or the German Witt museum online  
12 database to look for occurrence data.

13 **2. Known to feed on hosts of economic or environmental concern to the NAPPO**  
14 **region.**

15 There are a few online resources we have identified to help answer this question. First  
16 determine which host species the pest of interest targets:

17 Lepidopteran host plant database:

18 [http://www.nhm.ac.uk/our-science/data/hostplants/http://www.nhm.ac.uk/our-](http://www.nhm.ac.uk/our-science/data/hostplants/http://www.nhm.ac.uk/our-science/data/hostplants/)  
19 [science/data/hostplants/](http://www.nhm.ac.uk/our-science/data/hostplants/)

20 For some species, the Finland taxonomic database will have host information (usually  
21 near bottom of pest record):

22 <http://www.nic.funet.fi/pub/sci/bio/life/insecta/lepidoptera/ditrysia/noctuoidea/lymantriidae>

23 How to determine if economically important? If a pest feeds on a host included in a genus  
24 that has economic value in the NAPPO region, then it is a match.

25 Then cross-reference the host list with some resource that indicates distribution and status  
26 (crop, culturally significant, noxious weed, T&T, etc.) such as the USDA Plants database:

27 <http://plants.usda.gov/java/> or foreign trade data on forest products:  
28 <http://apps.fas.usda.gov/qats/default.aspx>

29

30 **3. Adult female moths attracted to light?**

31 When researching literature or museum collections, look for indication of whether the moth  
32 is caught in a light trap. Also, if a female is specifically caught in a light trap, we can also  
33 assume flight capable which will answer question7.

34 **4. Reports of contaminant during pest’s overwintering stage?**

35 Unless we can report the primary literature reference (or national interception data) that  
36 reports a contaminant event, we should report weakly reported risk associations (e.g. egg  
37 masses may be transported with lumber trade) using “Uncertain” and a value of zero. But  
38 use comments to document the possibility so that all data is retained.

39 **5. Reported to cause damage to trees of concern in native range, such that damage**  
40 **results in economic or environmental losses?**

41

42 **6. Larvae capable of ballooning?**

1 If there is no direct report of larval ballooning, we can investigate the morphological record  
2 for presence of secondary seta which indicates capacity to balloon.

3 **7. Adult females capable of flight?**

4 Evaluate the wing anatomy. With very few exceptions, full wing anatomy can be assumed  
5 to be flight capable. Vestigial wings will be answered as not flight capable, and no data,  
6 pictures, or info will be entered as "0" for uncertain. Also, there are odd exceptions like  
7 white spotted lymantriid, such that some generations can fly, and others have vestigial  
8 wings (and are incapable of flight).

9 **8. Life history contains dormant stage (diapause, aestivation, cryptobiosis) enabling  
10 organism to withstand harsh environmental conditions?**

11 **9. Capable of dispersing naturally more than 1km/year?**

12 Please report typical flight distance, ballooning distance, etc. in the comments.

13 **10. Reported to have allergenic properties?**

14 Severe allergenic reactions might include asthma, anaphylaxis, and blistering of the skin.  
15 Low to moderate reactions are not life threatening and may include skin rash, hives, runny  
16 nose, itchy eyes, and nausea.  
17  
18  
19

1 **Appendix 4. Example of a completed data sheet.**

2 **Species:** *Perina nuda* (Fabricius, 1787)

3 **Common name:** Clear-winged Tussock Moth

4 **Synonyms:** *Stilpnolia subtinca* Walker, 1855, *Perina basalis* Walker, 1855, *Euproctis combinata* Walker, 1865, *Perina pura* Walker, 1869, *Acanthopsyche ritsemae* Heylaerts, 1881

6 **Geographic Distribution:** Indian subregion, Sri Lanka, to Southern China, Hong Kong, Thailand and Sundaland.

Question	Answer	Score	Comments/References
Amount of the NAPPO region with similar climate types to where the species occurs	---	---	Potential Climate Match: Canada: 0%, Mexico: 13.55%, United States: 21.23%  Climate Types Affected: Af, Csc, Cwc (Butani, 1993; Peel <i>et al.</i> , 2007; Wakamura <i>et al.</i> , 2002; Zhang, 1994). Note: these were based on Koppen-Geiger climate types found in the majority of its distribution.
Known to feed on hosts of economic or environmental concern to the NAPPO region  Yes/No	Yes	---	<i>Perina nuda</i> feeds on <i>Ficus</i> spp. (fig) and <i>Mangifera indica</i> (mango) which are agricultural crops in the NAPPO region (Butani, 1993; NASS, 2014).
Adult female moths attracted to light  Yes (1) No (-1) Uncertain (0)	Yes	1	Moths were caught using a light trap (Khan <i>et al.</i> , 1988) but the gender was not specified. In another study male moths were captured in a light trap (Symonds <i>et al.</i> , 2012). Light trap collected females are reported from various collections. (Dave Holden pers. com)
Reports of contaminant during pest's overwintering stage  Yes, trade-related (2) Yes, non-trade (1) No (-2) Uncertain (0)	Uncertain	0	<i>Perina nuda</i> has never been intercepted at U.S. ports indicating it does not readily move in trade (PestID, 2017). Whether or not it can be transported in the overwintering stage is uncertain.
Reported to cause damage in native range, causing economic or environmental losses  Severe (3) Moderate (2) Low (1) None/Negligible (-2) Uncertain (0)	Severe	3	<i>Perina nuda</i> is a major pest of <i>Ficus</i> spp. in Taiwan (Wang and Tsai, 1995).
Larvae capable of ballooning  Yes (1) No (-1) Uncertain (0)	Uncertain	0	We found no evidence of this.
Adult females capable of flight  Yes (1) No (-1) Uncertain (0)	Yes	1	Female moths are winged (ICAR, 2017) indicating they are capable of flight.

Life history contains dormant stage to withstand harsh environmental conditions  Yes (1) No (-1) Uncertain (0)	Uncertain	0	We found no evidence of this.
Capable of dispersing naturally more than 1km/year  Yes (1) No (-1) Uncertain (0)	Uncertain	0	Moths were caught using a light trap (Khan <i>et al.</i> , 1988; Symonds <i>et al.</i> , 2012) indicating they can fly but specific flight distances were not found.
Reported to have allergenic properties  Yes (1) No (-1) Uncertain (0)	Uncertain	0	The larvae have urticating hairs that are used for defense (Cheanban <i>et al.</i> , 2017) but we did not find reports of <i>P. nuda</i> causing allergies in humans.
<b>TOTAL SCORE</b>		<b>5</b>
